Catalogue of the physical states

SU(2) lattice gauge theory with staggered quarks on 2x2, 2x3 and 2x4 ladders

Contents

1. How to read the pictures and the labels (pages 2-3)
2. Why a configuration can be unphysical: examples (page 4)
3. Energy levels of every sector, all three lattices (page 5)
4. Per lattice and baryon sector B: the ground state and excited states 1-3, each drawn as its
   dominant configurations with their weights
5. Every physical state of 2x2 (82) and 2x3 (1,727), drawn one by one, sector by sector

The 2x4 lattice has 37,165 physical states (about 2,000 pages if drawn); they are all listed with labels, bit strings and diagonal energies in the companion file reports/physical_states_catalogue_all_states.csv.

Number of physical states (gauge-invariant basis states) per baryon sector B

```
2x2: total     82   B=-2:2  B=-1:20  B=+0:38  B=+1:20  B=+2:2
2x3: total  1,727   B=-3:4  B=-2:95  B=-1:426  B=+0:677  B=+1:426  B=+2:95  B=+3:4
2x4: total 37,165   B=-4:8  B=-3:350  B=-2:2869  B=-1:8934  B=+0:12843  B=+1:8934  B=+2:2869  B=+3:350  B=+4:8
```

Model and parameters (src/skqd/hamiltonian.py)

```
H = sum_l hop_l  +  m sum_x (-1)^(x1+x2) n_x  +  (g^2/2) sum_l j_l(j_l+1)  -  1/(2 g^2) sum_P (W_P + W_P^dag)
```

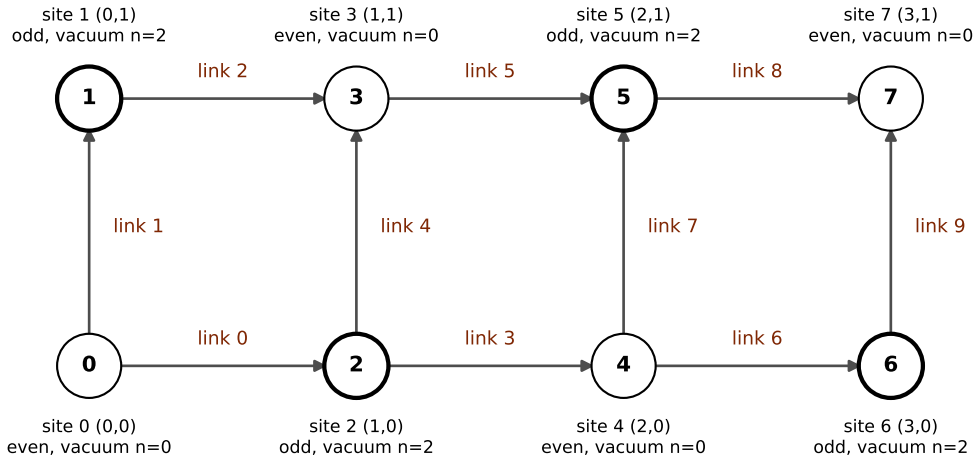

g^2 = 4, m = 3 g^2/16 = 0.75 (the package's standard line; the energies below are for these values), links truncated at j_max = 1/2 (each link has j = 0 or j = 1/2).

Where everything comes from

skqd.exact.Model(Lx) builds the gauge-invariant basis and the Hamiltonian; energies and eigenvectors are exact diagonalisations of each sector (numpy eigh, or scipy eigsh for the two large 2x4 sectors). Ground-state energies equal the stored references in validation/E3.json (checked on page 5). Bit strings: skqd.codec.Codec. Repository commit 261222c; generated 2026-10-28.

How to read the pictures

2x4 ladder (2x2 and 2x3 are its first 2 or 3 columns): site numbers, coordinates (x1, x2), link numbers and directions

Sites and quarks (staggered fermions)

* Each site holds a quark field with two colours, so its occupation is n = 0, 1 or 2 (number in the circle; white = 0, half-filled = 1, dark = 2).
* Staggered fermions: the 'empty' vacuum (Dirac sea) has n = 0 on EVEN sites (x1+x2 even, thin circle) and n = 2 on ODD sites (thick circle). Physical particles are deviations from that vacuum (brown label):

```
even site: n=0 -> nothing,  n=1 -> 'q' (one quark),       n=2 -> '2q' (two quarks)
odd site:  n=2 -> nothing,  n=1 -> 'q̄' (one hole = antiquark), n=0 -> '2q̄' (two holes)
```

* Mass term m sum (-1)^(x1+x2) n: every quark or antiquark costs energy m relative to the vacuum.

Links (colour-electric flux)

* Each link carries spin j = 0 (grey dashed, '0', no flux) or j = 1/2 (red, '½', one unit of flux). Electric energy (g^2/2) j(j+1) = 3/8 g^2 per flux link.

Gauss's law and the intertwiner iota

* At every site the spins arriving there (each flux link brings 1/2, n = 1 brings 1/2; n = 0, 2 bring 0) must combine to total colour spin 0. So the number of spin-1/2 objects at a site must be even.
* At an interior site with flux on all three links and n = 1 there are TWO ways to do this, labelled iota = 0, 1 (purple 'ι='); it is shown only there.

Baryon number B and sectors

* B = 1/2 sum_x (n_x - n_vac,x). In SU(2) a 'baryon' is two quarks, so B = 1 means two extra quarks; quark-antiquark pairs (mesons) have B = 0. The Hamiltonian never changes B, so each B is a separate sector.
* The SKQD work of this project uses B = 0 (2B = 0) and B = 1 (2B = 2).

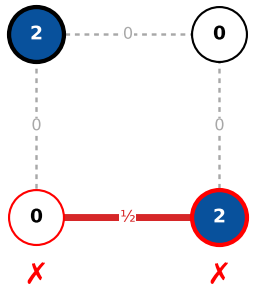

The text under each picture

* #k = position in the package's basis list (skqd.basis); '#i in sector' = position inside its B sector.
* E_diag = diagonal energy of that configuration alone (mass + electric terms) -- not an eigenvalue.
* bits = how the state is stored on qubits (skqd.codec): one group per site 0, 1, 2, ...; in each group the flux bits of the site's links (link-number order), then the matter bit (n/2, or iota at a three-flux n = 1 site).
* n=(...) per site, j=(...) per link in link-number order.
* In the eigenstate sections: c = amplitude of that configuration in the eigenstate (global phase fixed so the largest amplitude is real and positive) and |c|^2 = its weight (probability).

Examples of unphysical configurations (2x2 ladder)

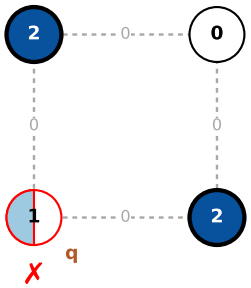

A configuration is physical only if Gauss's law holds at EVERY site: the spin-1/2 objects there (flux links and an n = 1 quark) must combine to total spin 0. Each example below is checked against the package: it is not in the basis, and skqd.vertex.kernel_dim = 0 (no singlet) at the marked site.

(a) Open flux string

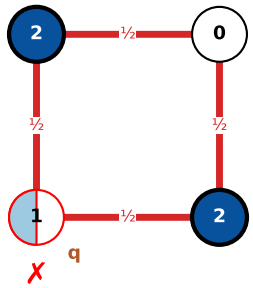

One flux link with nothing at its ends: each end site has a single spin-1/2 and no partner, so no singlet exists. Flux must close into a loop or end on a quark.

(b) Lone quark

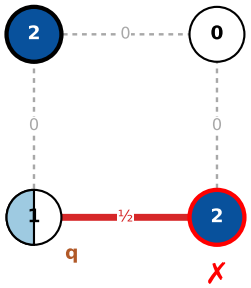

One quark (n=1) on site 0 with no flux: an isolated colour charge. Its spin-1/2 has nothing to pair with.

(c) Flux loop with a stray quark

A closed flux loop is fine by itself, but site 0 also has one quark: two flux links + one quark = three spin-1/2 objects, an odd number, so no spin 0.

(d) String with only one end on a quark

Site 0 is fine (flux + quark pair up), but the other end of the string, site 2, has nothing to pair with. A string must end on charges at BOTH ends (compare a valid meson: also n = 1 at site 2).

Bit strings that are not states (rejected by the decoder, skqd.codec.Codec.decode)

The qubit encoding can also produce strings that describe no state at all; the decoder rejects them:

```
good  000 000 001 001   = state #3: decoder 'accepted'
link  100 000 001 001   one copy of link 0 changed: the two ends disagree -> 'link'
flag  011 100 000 000   corner with one flux must have n = 1, matter bit 1 is a flag -> 'flag'
```

* 'link': every link is stored at both of its ends; a physical state has equal copies.
* 'flag': a matter-bit value that the site's flux pattern does not allow (n is already forced).
* 'sector': a perfectly physical state, rejected only because its baryon number B is not the one being studied.
  It is NOT unphysical -- it belongs to another sector of this catalogue.

Unphysical configurations like (a)-(d) cannot even be written in this encoding: the encoding stores only Gauss-law-respecting site states (6 per corner site, 13 per interior site), which is why bit-level errors show up as 'link' or 'flag' rejections instead.

Energy levels of every sector (g^2 = 4, m = 0.75)

E_0 = ground state, E_1, E_2, E_3 = first three excited states. '=' marks a degenerate level (same energy as its neighbour); inside a degenerate level the choice of individual eigenvectors is arbitrary.

Check: stored references validation/E3.json (key 2xL|g2=4.0|2B=...) vs this computation.

2x2, sector B = -2 (2 physical states)

Lowest energy levels and how each one is drawn on the following pages

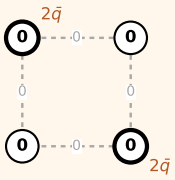

E_0 = -0.010399 (ground state): 1 configurations drawn carry 99.8% of the weight; participation ratio 1.0

E_1 = +6.010399 (excited state 1): 1 configurations drawn carry 99.8% of the weight; participation ratio 1.0

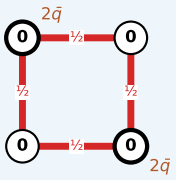

Each eigenstate is a superposition of many configurations. The following pages draw its most important configurations (largest weight first, up to 6 or until 95% of the weight is covered), one card each, with the amplitude c and the weight |c|^2. Cards of the same level share a background colour.

Participation ratio = 1/sum|c|^4 = roughly how many configurations the state is spread over.

2x2, B = -2: lowest eigenstates, dominant configurations (page 1/1)

#0 (B=-2, #0 in sector) E_diag = +0.000
E_0 (ground state): c = +0.9991, |c|² = 0.9983
bits 000 000 000 000
n=(0 0 0 0) j=(0 0 0 0)

#66 (B=-2, #1 in sector) E_diag = +6.000
E_1 (excited state 1): c = +0.9991, |c|² = 0.9983
bits 110 110 110 110
n=(0 0 0 0) j=(½ ½ ½ ½)

2x2, sector B = -1 (20 physical states)

Lowest energy levels and how each one is drawn on the following pages

E_0 = -1.861588 (ground state): 5 configurations drawn carry 95.6% of the weight; participation ratio 2.6

E_1 = -1.819745 (excited state 1): 4 configurations drawn carry 95.3% of the weight; participation ratio 2.4

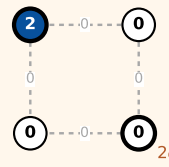

E_2 = +0.208229 (excited state 2): 6 configurations drawn carry 76.0% of the weight; participation ratio 8.1

E_3 = +0.450558 (excited state 3): 6 configurations drawn carry 71.4% of the weight; participation ratio 8.9

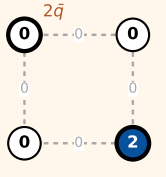

Each eigenstate is a superposition of many configurations. The following pages draw its most important configurations (largest weight first, up to 6 or until 95% of the weight is covered), one card each, with the amplitude c and the weight |c|^2. Cards of the same level share a background colour.

Participation ratio = 1/sum|c|^4 = roughly how many configurations the state is spread over.

2x3, sector B = +0   (677 physical states)

Lowest energy levels and how each one is drawn on the following pages

E_0 = -5.602600 (ground state): 6 configurations drawn carry 89.1% of the weight; participation ratio 1.9

E_1 = -2.888603 (excited state 1): 6 configurations drawn carry 61.1% of the weight; participation ratio 12.2

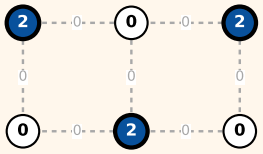

E_2 = -2.865178 (excited state 2): 6 configurations drawn carry 68.2% of the weight; participation ratio 9.7

E_3 = -2.777016 (excited state 3): 6 configurations drawn carry 64.4% of the weight; participation ratio 11.2

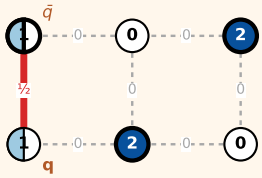

Each eigenstate is a superposition of many configurations. The following pages draw its most important configurations (largest weight first, up to 6 or until 95% of the weight is covered), one card each, with the amplitude c and the weight |c|^2. Cards of the same level share a background colour.

Participation ratio = 1/sum|c|^4 = roughly how many configurations the state is spread over.

2x4, sector B = -2 (2,869 physical states)

Lowest energy levels and how each one is drawn on the following pages

E_0 = -3.988089 (ground state): 6 configurations drawn carry 87.4% of the weight; participation ratio 2.0

E_1 = -3.852621 (excited state 1): 6 configurations drawn carry 75.3% of the weight; participation ratio 7.5

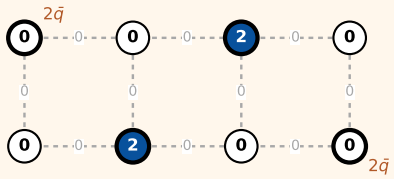

E_2 = -3.851970 (excited state 2): 6 configurations drawn carry 78.3% of the weight; participation ratio 6.3

E_3 = -3.813863 (excited state 3): 6 configurations drawn carry 80.6% of the weight; participation ratio 5.8

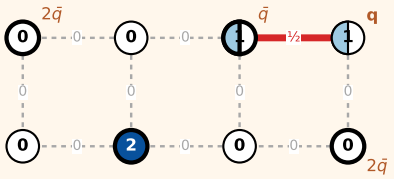

Each eigenstate is a superposition of many configurations. The following pages draw its most important configurations (largest weight first, up to 6 or until 95% of the weight is covered), one card each, with the amplitude c and the weight |c|^2. Cards of the same level share a background colour.

Participation ratio = 1/sum|c|^4 = roughly how many configurations the state is spread over.

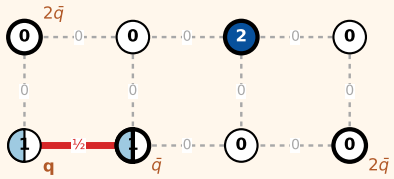

2x4, B = -2: lowest eigenstates, dominant configurations (page 1/2)

2x4, sector B = +0 (12,843 physical states)

Lowest energy levels and how each one is drawn on the following pages

E_0 = -7.565214 (ground state): 6 configurations drawn carry 77.9% of the weight; participation ratio 2.5

E_1 = -4.843599 (excited state 1): 6 configurations drawn carry 52.8% of the weight; participation ratio 16.3

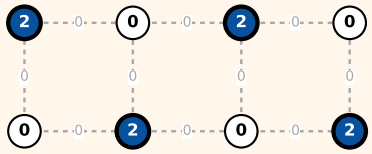

E_2 = -4.837465 (excited state 2): 6 configurations drawn carry 57.6% of the weight; participation ratio 13.3

E_3 = -4.736602 (excited state 3): 6 configurations drawn carry 42.7% of the weight; participation ratio 20.9

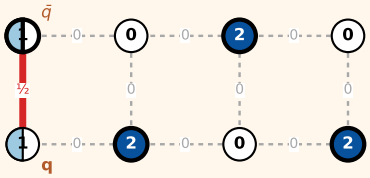

Each eigenstate is a superposition of many configurations. The following pages draw its most important configurations (largest weight first, up to 6 or until 95% of the weight is covered), one card each, with the amplitude c and the weight |c|^2. Cards of the same level share a background colour.

Participation ratio = 1/sum|c|^4 = roughly how many configurations the state is spread over.

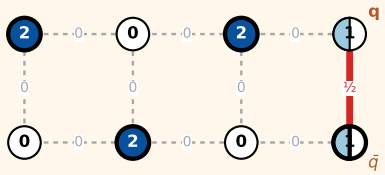

2x4, B = +0: lowest eigenstates, dominant configurations (page 1/2)

2x4, sector B = +2 (2,869 physical states)

Lowest energy levels and how each one is drawn on the following pages

E_0 = -3.988089 (ground state): 6 configurations drawn carry 87.4% of the weight; participation ratio 2.0

E_1 = -3.852621 (excited state 1): 6 configurations drawn carry 75.3% of the weight; participation ratio 7.5

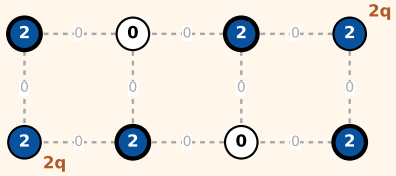

E_2 = -3.851970 (excited state 2): 6 configurations drawn carry 78.3% of the weight; participation ratio 6.3

E_3 = -3.813863 (excited state 3): 6 configurations drawn carry 80.6% of the weight; participation ratio 5.8

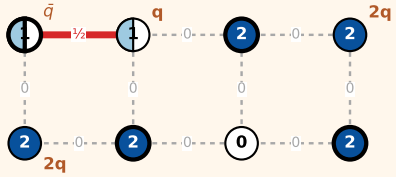

Each eigenstate is a superposition of many configurations. The following pages draw its most important configurations (largest weight first, up to 6 or until 95% of the weight is covered), one card each, with the amplitude c and the weight |c|^2. Cards of the same level share a background colour.

Participation ratio = 1/sum|c|^4 = roughly how many configurations the state is spread over.

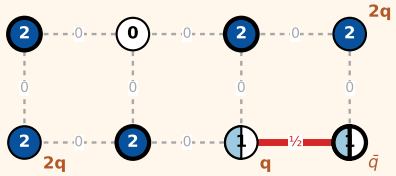

2x4, B = +2: lowest eigenstates, dominant configurations (page 1/2)
